THERMODYNAMIC AND RELATED PROPERTIES OF OXYGEN FROM THE TRIPLE POINT TO 300 K AT PRESSURES TO 1000 BAR

L. A. Weber

NBS compressibility measurements and thermodynamic properties calculations for oxygen have been extended to higher pressures. The results of a new experimental program are presented in the form of PVT data in the temperature range 58 - 300 K at pressures up to 800 bar. Tables of the derived thermodynamic properties on isobars to 1000 bar are given, including density, internal energy, enthalpy, entropy, specific heats at constant volume and constant pressure, velocity of sound, and the surface derivatives $(\partial P/\partial T)_\rho$ and $(\partial P/\partial \rho)_T$. Auxiliary tables in engineering units are also given. The accuracy of the data is discussed and comparisons are made with previous data.

Key words: Density; enthalpy; entropy; oxygen; properties of fluids; specific heat; velocity of sound.

1. Introduction

Approximately eight years ago this laboratory began publishing a series of papers on experimental measurements of the properties of oxygen in the range from the triple point (approximately 54 K) to 300 K at pressures up to about 340 bar. Included in this series were measurements of PVT data and derived thermodynamic properties [1], specific heats [2,3], velocity of sound [4], dielectric constant [5], viscosity [6], vapor pressure [7] and critical region behavior [8]. Recent developments in the design of spacecraft engines, however, have resulted in the need for thermophysical properties data at higher pressures. In an earlier, interim report [9], we extrapolated the above results to 690 bar. In this report we present new PVT measurements to 800 bar and the thermodynamic properties derived from them. Approximately 348 PVT data points were measured at 38 densities ranging from 15 to 41 mol/ℓ (0.48 - 1.3 g/cm^3).

The data have been represented analytically for the purpose of interpolation and to allow calculation of the thermal properties. The tables of derived

*This work was carried out at the National Bureau of Standards under the sponsorship of the National Aeronautics and Space Administration.

properties have been extrapolated to 1000 bar. The results have been compared with published data in this temperature and pressure range.

2. Experimental Method

2.1 Description of the Apparatus

The apparatus, which was designed to make PVT measurements on isochores (lines of constant density) was originally described by Goodwin [10]. Later modifications were described by Weber [1] and by Prydz and Straty [11]. Only a brief description will be given here. The sample holder is a heavy-walled copper cylinder of approximately 5 cm O.D. and 1.6 cm I.D. The volume of the cavity is 27.25 cm^3. Corrections are made for the change in volume with temperature and pressure. The sample is introduced, and the pressure is measured, via a stainless steel capillary having an I.D. of about 0.033 cm. Temperature is measured with a platinum resistance thermometer mounted in a well in one end. The sample holder is mounted in a nearly adiabatic cryostat, and the small amount of residual cooling is balanced by means of a temperature controller and a heater wire wrapped around the outside of the container. Pressure is measured with an oil-operated dead weight gage described in detail in [1]. Corrections were made for the hydrostatic pressure head in the capillary tubing. Density was determined by releasing the sample into a 22 ℓ calibrated glass bulb maintained at room temperature in a thermostated water bath. Pressure in the glass bulb was measured with a quartz spiral bourdon gage.

Samples came from commercially available cylinders of ultra high purity oxygen which was passed through a molecular sieve trap at 76 K at cylinder pressure to remove any water. The statement of purity from the supplier is as follows: argon 3 ppm, nitrogen 20 ppm, krypton 16 ppm, total hydrocarbons 17 ppm.

2.2 Experimental Procedure

The sample was passed through the molecular sieve trap and loaded into the sample holder at a predetermined temperature and pressure, calculated to yield the desired experimental density. The sample holder was sealed off by means of a stainless steel valve mounted on top of the cryostat. The measurement system then consisted of the sample holder, a length of capillary tubing with a volume

of 0.068 cm^3, the valve, volume of 0.024 cm^3, and a differential pressure transducer with a volume of 0.30 cm^3. Pressure was then measured as a function of temperature at a set of integral temperatures along a path of nearly constant density. When the maximum temperature or pressure was reached, the sample was released into the glass bulb. Measurement of the gas pressure in the bulb along with available room temperature virial coefficients allowed calculation of the amount of sample, and thus the density.

3. Experimental Results

3.1 The Data

The data consist of 348 points taken along 38 lines of (approximately) constant density (experimental isochores). Data on each isochore were taken on the same set of temperatures so that the result would be a set of experimental isotherms. A two degree spacing was used up to a temperature of 160 K, then a five degree interval up to 200 K, and a ten degree interval to 300 K. All temperatures were measured on the IPTS 1968 scale. For each experimental density one or more points were measured at pressures less than 340 bar, within the range of the data in reference [1] to check the consistency of the two data sets. The results of this check are discussed in section 3.3.

The data are given in table I, and their location with respect to the earlier data is shown in figures 1 and 2.

3.2 Representation of the Data

The present data were combined with those from [1] to define the PVT surface used for the calculation of the thermodynamic properties. The earlier data were measured on the IPTS 1948 temperature scale and, below 90 K, on the NBS 1955 scale, and it was therefore necessary to convert them to the IPTS 1968 scale for the present work. This was accomplished by modifying the experimental pressures using the relationship,

$$\Delta P = \left(\frac{\partial P}{\partial T}\right)_{\rho} (T_{68} - T_i) \qquad (1)$$

where T_i was the temperature on either of the previously used scales. In this

way the tabulated values of the temperature were not changed, and all the data could be fit to the same set of isotherms. The temperature conversion tables were taken from [12].

For the purpose of representation the PVT surface was divided into three regions, and each region was smoothed and interpolated by the means which seemed most appropriate. Location of the three regions is shown in figure 3, and they are discussed separately below. Each data point was given a weight compatible with the estimated uncertainties in the experimental variables.

Low Density Region. A virial-type expansion in density insures proper behavior of the entropy calculations at very low density and so was used here. A truncated virial expression with two coefficients,

$$P = RT\rho\ (1 + B\rho + C\rho^2) \tag{2}$$

represented the data very well up to a density one half the critical value. The virial coefficients, B and C, were expressed as low-order polynomials in temperature, and equation (2) was fit to the data in the form of an analytic surface. In addition to the PVT data, 14 experimental values of C_v at a density of 6.1 mol/ℓ were included in the fitting process. None of the new data fall within the range of equation (2) and so in the present work the data of [1] were merely refit on the IPTS 1968 temperature scale. The functions and parameter values used for B and C are given in Appendix A.

Intermediate Densities. The data between 128 K and 300 K at densities greater than 6.5 mol/ℓ up to the maximum experimental pressure were represented by 35 isotherm polynomials of the form

$$P = RT\rho + \sum_{J=1}^{N} A_J \rho^{(J+1)}. \tag{3}$$

The number of coefficients used varied from four to a maximum of 14 for the 156 K isotherm. These isotherms were used to smooth the data and to interpolate it to even increments of density. The pressure-temperature pairs so obtained for a given density were then fit with an isochore polynomial of the form,

$$P = \sum_{J=1}^{5} A_J T^{(3-2J)} \quad . \tag{4}$$

A total of 62 isochore polynomials were used to cover the density range from 6.5 to 37.0 mol/ℓ, using a 0.5 mol/ℓ increment in density. The intermediate densities then were represented by a grid of isotherm and isochore polynomials. The parameters used in equations (3) and (4) are given in tables II and III, respectively.

At subcritical temperatures the isotherms were constrained to agree with the liquid-vapor two phase boundary given in Appendix B. The isochores were also constrained to this boundary. For densities greater than 28.5 mol/ℓ isochores were constrained to have their second derivatives, $(\partial^2 P/\partial T^2)_\rho$, agree at 128 K with the values given by the high density surface in the next section. This was done to minimize discontinuities in the derived properties at this boundary in the surface representation.

High Densities. The high density region, bounded in figure 3 by the melting curve, vapor pressure curve, and the 128 K isotherm, was represented with a fourteen parameter empirical function of the form,

$$\begin{aligned} P = {} & RT\rho + (A_1 T^2 + A_2 T + A_3 + A_4/T) + (A_5 T^2 + A_6 T + A_7 + A_8/T \\ & + A_9/T^2)\rho + (A_{10} T^2 + A_{11} T + A_{12})\rho^2 + (A_{13} T^2 + A_{14} T)\rho^3 \quad . \end{aligned} \tag{5}$$

The values of the parameters are given in table IV. In addition to the PVT data, some of the specific heat data from [3] were included in the fit. These were used to influence the derivatives of the surface and ensure more accurate calculation of the derived thermodynamic properties.

Other Data. The melting pressures and liquid-vapor two phase boundary, were taken from [1], and the critical parameters were taken from [8]. The data were converted to the IPTS 1968 temperature scale and the curves were refit. The vapor pressure curve from [7], refit on the IPTS 1968 scale, was also used. The functions are repeated here in Appendix B with the new coefficients for the convenience of the reader.

Interpolation Methods for Densities. Equations (2-5) are all explicit in pressure. Therefore the density at a given temperature and pressure was found by iteration. In the high and low density regions a simple Newton's iteration was used along the appropriate isotherm of the analytic surfaces, equations (2) or (5). In the intermediate density region, densities were found by iterating on the isotherms tabulated in table II. For a temperature falling between two tabulated isotherms a linear interpolation between the two bracketing isotherms would be adequate.

Saturation densities at temperatures greater than 128 K in the liquid, or greater than 150 K for the vapor, were calculated from the functions given in Appendix B(e). The appropriate isotherm and isochore polynominals were constrained to this boundary in order to insure consistency between the two-phase boundary and the one-phase surface. At lower temperatures this consistency is assured by allowing the saturation densities to be determined from the intersection of the PVT surfaces, equations (2) and (5), with the vapor pressure curve. These surfaces were constrained to agree with the equations in Appendix B(e) at 150 K and 128 K respectively in order to eliminate discontinuities at these points.

3.3 Estimates of Uncertainty of the PVT Data

In references [1,10,11] and several other publications of this laboratory considerable attention has been given to the determination of the volume of the sample holder, which is of primary importance in the measurement of the density. The results of several workers over a period of years indicates that we can determine this volume with an accuracy of about 0.1%. The uncertainty in the external volumes connected to the sample holder is estimated to be 0.01 cm^3. The effect on the density of this uncertainty varies from 0.036% for the room temperature gas data to a negligible amount for low pressure liquid data. Corrections made to the sample holder volume for pressure and temperature effects are estimated to add several hundredths of one percent at the highest pressure and lowest temperatures. The volume of the 22 ℓ glass bulb is known to within 0.04%. The accuracy of the dead weight pressure gage is 0.01 - 0.02%, and errors due to this source are negligible in the range of the present data. Temperature measurements had precision and reproducibility within 0.001 K. However, the overall accuracy of the potentiometer used leads to uncertainties in the absolute

temperatures which vary from 0.002 K at 50 K to 0.028 K at room temperature. From the above considerations the overall maximum uncertainty varies from about 0.1% for the low temperature, low pressure liquid data to about 0.17% for the high pressure, room temperature gas data. The experimental precision is about 0.02% in density.

For the purpose of this report it was considered most important that the new data show no appreciable systematic deviations from the data of [1]. For this reason, on almost every experimental isochore, one or more points were measured at pressures within the range of the data of [1] and comparisons were made with the earlier PVT surface representation. In this way the compatibility of the two data sets was monitored during the course of the measurements.

In recent PVT measurements on parahydrogen [13] the sample holder had been subjected to pressures as high as 850 bar. The volume was observed to have expanded inelastically by about 5%. In the present work, the above compatibility measurements indicated that the volume underwent further "slippage" by small amounts on three occasions. Each change could be correlated closely with some of the highest pressures attained during the work. The only reasonable conclusion is that the elastic limit of the sample holder occurs at a pressure of about 800 bar. The first 16 experimental runs correlate well with the data of [1] using the initial volume calibration. The next four runs show an average systematic deviation from the earlier data of 0.16%. After run 20 the deviation averaged 0.22%, and after run 29 the deviation increased to about 0.72%. The volume of the sample holder was adjusted by the above amounts, and the corresponding density adjustments have been incorporated into the data given in table I.

The above uncertainties apply to the experimental data. The PVT surface representations, discussed earlier in this section, have been incorporated into a computer program used to interpolate density and to calculate the derived thermodynamic properties. The last column in table I, expressed as percent difference in density, indicates how well this program reproduces the experimental data.

3.4 Comparisons With Other Data

The present data have been compared with the oxygen PVT surface given in [1]. The 56 points at pressures less than 350 bar exhibited an average deviation of

+ 0.04% in density from our earlier surface.

Comparisons with earlier published data at pressures less than 330 bar have been given in [1] and are not repeated here. Streett and Sagan [14] have published more recent densities on six isotherms between 96 and 250 K at pressures to 684 atm. They calibrated the volume of their apparatus by comparing their results with ours from [1] at low pressures at 100 K. Thus the results of the two laboratories should be compatible. The differences between their experimental results and the values interpolated from our PVT surface are shown in figure 4. The agreement between the compressed liquid data, 96 - 110 K, is seen to be good, with perhaps a slight systematic trend with pressure. The compressed fluid data between 170 K and 250 K agree less well. These differences may be due, as they stated, to the thermal expansion correction applied to the volume of their sample holder. Their container is made of maraging steel, for which the thermal expansion is only approximately known at low temperatures. Since the data sets were forced to agree at 100 K, the largest disagreement would be expected at the highest temperature. In addition, our own data has a larger uncertainty at the higher temperatures due to the larger effect of the corrections for the external volumes.

The vapor pressure equation used here is a refit of Goodwin's equation [7] on the IPTS-68 scale. It has been extensively compared with the most recent data and with other equations by Wagner, et al. [15]. The agreement is quite good for temperatures above 85 K. However, equations fit to the older data (pre 1968) exhibit deviations from the latest data which approach a maximum of 0.15% at 70 K. The newest data were measured with thermometers calibrated on the IPTS-1968 temperature scale while the older data were converted to this scale by means of published conversion tables. The systematic chronological difference may suggest that there is a small incompatibility between these two methods of arriving at IPTS 1968 temperatures. Prydz's fit of Goodwin's equation used a value of 148 N/m^2 for the triple point pressure, while the present version uses an average of the best recent experimental determinations, 146.4 N/m^2. The triple point temperature used here, 54.359 $\pm$ .002 K, is that measured with our thermometer. It agrees with the accepted IPTS 1968 value of 54.361 K within its uncertainty.

3.5 Thermodynamic Properties

Many equilibrium thermodynamic properties can be derived from the PVT surface by means of well-known relationships. These relationships and the calculation techniques used here have been given in [1], and they will not be repeated. Knowledge of the PVT surface allows the calculation of the isothermal change in a property with density, and to this must be added the value of that property in the ideal gas state at the corresponding temperature. The thermodynamic properties of the ideal gas are taken from Woolley [16] and the equations used here are given in Appendix B. In addition, changes in properties with temperature may be calculated via specific heat data, and use is made of the specific heat data from [2,3] on a particular density, 28.687 mol/ℓ, to allow calculations in the compressed liquid without the necessity of crossing the vapor-liquid boundary. The results are tabulated for the liquid-vapor coexistence boundary in table Va and along isobars from 1-1000 bar in table VIa. The same properties are also tabulated in engineering units in tables Vb and VIb, respectively. Properties tabulated include specific volume, internal energy, enthalpy, entropy, specific heats at constant volume and at constant pressure, sound velocity, and the surface derivatives $(\partial P/\partial \rho)_T$ and $(\partial P/\partial T)_\rho$.

The derived properties were compared in [1] with existing, published experimental measurements. Comparisons here are confined to those with more recent experimental results, measurements at pressures greater than 350 bar, and regions where our surface representation has been modified substantially. Goodwin and Weber [3] measured single phase C_v data at 19 densities between 0.45 and 3 times critical density. After deleting one, apparently incorrect, C_v isochore and several points near critical, the remaining 131 data points were compared with values calculated from the PVT surface. The average of the absolute values of the relative deviations was 0.89%. Goodwin and Weber also estimated the maximum uncertainty for each experimental point. If we divide the difference, |calculated minus experimental C_v|, by this estimated experimental uncertainty and average over all the data, the average is 1.05. Thus the C_v data are reproduced to within their experimental uncertainty. For the data close to the critical point the differences increase to over 20%. This is not surprising since the present representation corresponds to an analytic surface which cannot lead to accurate specific heats in the near vicinity of the critical point.

Calculation of the entropy of the saturated liquid at the triple point begins with the entropy of the ideal gas at 160 K, from [15], and follows a rather complicated path, detailed in [1]. The value arrived at is 67.11 J/mol-K. This value may be compared with the one from Giauque and Johnston [17], 67.10 $\pm$ 0.15 J/mol-K, found by integrating their specific heat data for solid oxygen and using their value for the heat of fusion at the triple point. This comparison may be used to indicate the agreement between these two experiments and the third law of thermodynamics. It also serves as an independent check on the reliability of the derived properties of the saturated liquid. Uncertainties in the enthalpy and internal energy of the saturated liquid may also be estimated by comparing the three different ways of calculating the heat of vaporization with the available experimental measurements. This is done in table VII. Here the ΔH is the vapor enthalpy less the liquid enthalpy as given in table Va. The agreement with the quantities $T\Delta S$ and the value of ΔH calculated via the Clapeyron equation indicates that there are no appreciable errors in the vapor pressure curve. From the above comparisons the uncertainty in the enthalpy of the saturated liquid is estimated to be no more than 10 J/mol. A careful consideration of the effects of the PVT surface indicates that this uncertainty increases to 15 J/mol at a pressure of 800 bar. In the supercritical gas phase the enthalpy calculations begin at zero pressure with the ideal gas value, which has negligible uncertainty. At 300 K the uncertainty increases to 6 J/mol at a pressure of 200 bar, 10 J/mol at 400 bar, and 16 J/mol at 800 bar. These statements of accuracy would also apply to the internal energy. Uncertainties in all quantities are greater in the critical region.

Calculated values of the velocity of sound have been compared with the experimental results of Van Itterbeek and Van Dael [18] and with Straty and Younglove [4]. These comparisons are shown in figures 5 and 6. It is seen that the agreement is generally good at supercritical temperatures, but there is a systematic trend which leads to differences up to about 1% at 350 bar, the maximum experimental pressures. This trend is also evident in the liquid where the agreement is less good, eventually reaching 3.8% at 68 K and a pressure of 900 bar. The velocity of sound, W, is calculated via the relationship,

$$W = \left[\left(\frac{\partial P}{\partial \rho}\right)_T + \frac{T}{\rho^2 C_v}\left(\frac{\partial P}{\partial T}\right)_\rho^2\right]^{1/2}, \qquad (6)$$

from which it is seen that this comparison constitutes a fairly severe test of the surface derivatives. This is especially true in the highly incompressible liquid phase where small changes in the volume of a system result in relatively large pressure changes. Thus small systematic errors in the volumes of the PVT system could lead to systematic errors in the surface derivatives used in (6). Additional errors are undoubtedly introduced by the necessary analytical representation used for ths surface.

4. Summary

Experimental PVT measurements have been made at pressures up to about 800 bar. The data were represented analytically, and the resulting PVT surface was used to derive thermodynamic properties. The uncertainties in the experimental and derived properties were analyzed, and the results were compared with other published data for oxygen.

5. Acknowledgments

The author is indebted to D. E. Diller and G. C. Straty for many helpful discussions and to R. D. McCarty for the least-squares program used here. This work was supported by NASA Contract C-32369-C.

Appendix A. Parameters for the Second and Third Virial Coefficients (low density region, equation (2) in text)

(a) Second virial coefficient, in (cm^3/mol).

$$B = \sum_{J=1}^{5} B_J \, T^{(1 - J)/4}$$

$$\begin{aligned} B_1 &= -8.638\,001\,288 \times 10^2 \\ B_2 &= 1.733\,064\,315 \times 10^4 \\ B_3 &= -1.241\,961\,054 \times 10^5 \\ B_4 &= 3.956\,609\,285 \times 10^5 \\ B_5 &= -4.904\,475\,356 \times 10^5 \end{aligned}$$

(b) Third virial coefficient, in $(cm^3/mol)^2$.

$$C = \sum_{J=1}^{6} C_J \, T^{(1 - J)/2}$$

$$\begin{aligned} C_1 &= 3.569\,552\,013 \times 10^5 \\ C_2 &= -2.696\,578\,423 \times 10^7 \\ C_3 &= 8.152\,809\,009 \times 10^8 \\ C_4 &= -1.229\,796\,911 \times 10^{10} \\ C_5 &= 9.252\,345\,993 \times 10^{10} \\ C_6 &= -2.771\,904\,509 \times 10^{11} \end{aligned}$$

Appendix B. Fixed Points and Phase Boundaries, Thermal Properties of Ideal Gas and Real Gas at STP

(a) Triple Point:

$$T_t = 54.359 \pm .002 \text{ K}$$
$$P_t = 0.001464 \text{ bar}$$
$$\rho_t(\text{liquid}) = 0.04083 \text{ mol/cm}^3$$

(b) Normal Boiling Point:

$$T_b = 90.188 \text{ K}$$
$$P_b = 1.0 \text{ atm} = 1.01325 \text{ bar}$$
$$\rho_b(\text{liquid}) = 0.03566 \text{ mol/cm}^3$$
$$\rho_b(\text{gas}) = 0.0001397 \text{ mol/cm}^3$$

(c) Critical Point:

$$T_c = 154.581 \text{ K}$$
$$P_c = 50.43 \text{ bar}$$
$$\rho_c = 0.01363 \text{ mol/cm}^3$$

(d) Melting Pressure: (bar)

$$P = P_t + P_o [(T/T_t)^c - 1]$$
$$P_o = 2672.27, \quad c = 1.769$$

(e) Liquid-Vapor Coexistence Densities, (mol/cm^3):

$$\rho_{SAT}(\text{liquid}) = \rho_{RD} + f(T)$$

$$\rho_{SAT}(\text{vapor}) = \rho_{RD} - f(T)$$

where

$$\rho_{RD} = \rho_c + a_1 (T_c - T) + a_2 (T_c - T)^2$$

$$f(T) = \rho_c \sum_{J=1}^{3} A_J \left(\frac{T_c - T}{T_c} \right)^{(2J-1)\beta}$$

$A_1 = 1.811\ 3127$ $\quad \beta = 0.353$

$A_2 = 2.775\ 1793 \times 10^{-1}$ $\quad a_1 = 6.0402 \times 10^{-5}$

$A_3 = -7.580\ 9408 \times 10^{-1}$ $\quad a_2 = 9.80 \times 10^{-8}$

The above relations were used from 150 K to T_c for the vapor, and from 128 K to T_c for the liquid. Below these temperatures the densities were found by the intersection of equations (2) or (5), respectively with the vapor pressure curve.

(f) Vapor Pressure:

$$\ln(P/P_t) = A\chi + B\chi^2 + C\chi^3 + D\chi(1 - \chi)^{\varepsilon}$$

$$\chi = (1 - T_t/T)/(1 - T_t/T_c)$$

$A = 7.797\ 7723$

$B = 4.577\ 3000$

$C = -1.928\ 1264$

$D = 3.293\ 1232$

$\varepsilon = 1.5$

(g) Molecular Weight of Oxygen: 31.9988 g/mol:

(h) Ideal Gas Thermodynamic Properties:

$$\frac{C_p^o(T)}{R} = \sum_{J=1}^{7} A_J T^{(J-4)} + A_8 \frac{u^2 e^u}{(e^u - 1)^2}$$

where $u = A_9/T$

$A_1 = -1.86442361 \times 10^2$ $\quad A_6 = -1.11035799 \times 10^{-8}$

$A_2 = 2.07840241 \times 10$ $\quad A_7 = 2.08612876 \times 10^{-11}$

$A_3 = -3.42642911 \times 10^{-1}$ $\quad A_8 = 1.01894691$

$A_4 = 3.50297163$ $\quad A_9 = 2.23918105 \times 10^3$

$A_5 = 2.05866482 \times 10^{-7}$

At T = 55 K, P = 1 atm

H° = 49.718 J/g

S° = 4.8696 J/g-K

(i) Real Gas Thermodynamic Properties at Standard Conditions (T = 273.15 K, P = 1 atm)

H = 248.07 J/g

S = 6.328 J/g-K

Appendix C. Brief History of the PVT Sample Holder

The PVT sample holder used previously by this laboratory has now been retired and replaced by a new one. It therefore seems appropriate to summarize its history. The design, fabrication and original calibration were performed by R. D. Goodwin, and the descriptions are given by him in ref. [10]. Briefly, it is a heavy-walled cylindrical container made of electrolytic tough pitch copper, having the dimensions 2" O.D., 5/8" I.D., wall thickness 11/16", and length 8 1/2". A heater wire was wrapped around the cylinder, and a platinum thermometer well was drilled in the top end. The sample cavity (5/8" by approximately 5") had a volume of about 25.85 cm^3 at standard conditions. A stainless steel capillary tube (0.013" I.D.) was used for filling and for communication with the pressure gauge.

This sample holder has been used for measurements (in chronological order) on p-H_2 [20], O_2 [1], F_2 [11], CH_4 [21], p-H_2 [13], C_2H_6 [22], and the present work on oxygen. All measurements were made at pressures up to about 350 bar except ref. [13] and the present work. Independent volume calibrations from the first four references above indicated an average volume of 25.88 $\pm$ 0.03 cm^3. Later, in ref. [13] it was pressured to 850 bar and the volume expanded inelastically by 5.2%. In this work experimental pressures of 795-817 bar were attained on several occasions, resulting in further increases in the volume totaling 0.7%. Thus we conclude that these measurements define the elastic limit of a vessel of these dimensions and construction.

Table IV. Parameters for Equation (5)

$A_1 = 2.163\ 315\ 605$

$A_2 = -4.951\ 878\ 499 \times 10^{2}$

$A_3 = 2.218\ 375\ 056 \times 10^{4}$

$A_4 = -5.257\ 882\ 219 \times 10^{4}$

$A_5 = -1.747\ 330\ 429 \times 10^{2}$

$A_6 = 3.800\ 674\ 644 \times 10^{4}$

$A_7 = -1.275\ 638\ 488 \times 10^{6}$

$A_8 = 2.485\ 625\ 682 \times 10^{6}$

$A_9 = -2.677\ 274\ 930 \times 10^{7}$

$A_{10} = 4.814\ 034\ 026 \times 10^{3}$

$A_{11} = -9.872\ 472\ 202 \times 10^{5}$

$A_{12} = 1.603\ 575\ 028 \times 10^{7}$

$A_{13} = -4.659\ 223\ 596 \times 10^{4}$

$A_{14} = 9.412\ 696\ 699 \times 10^{6}$

$R = 82.0597$

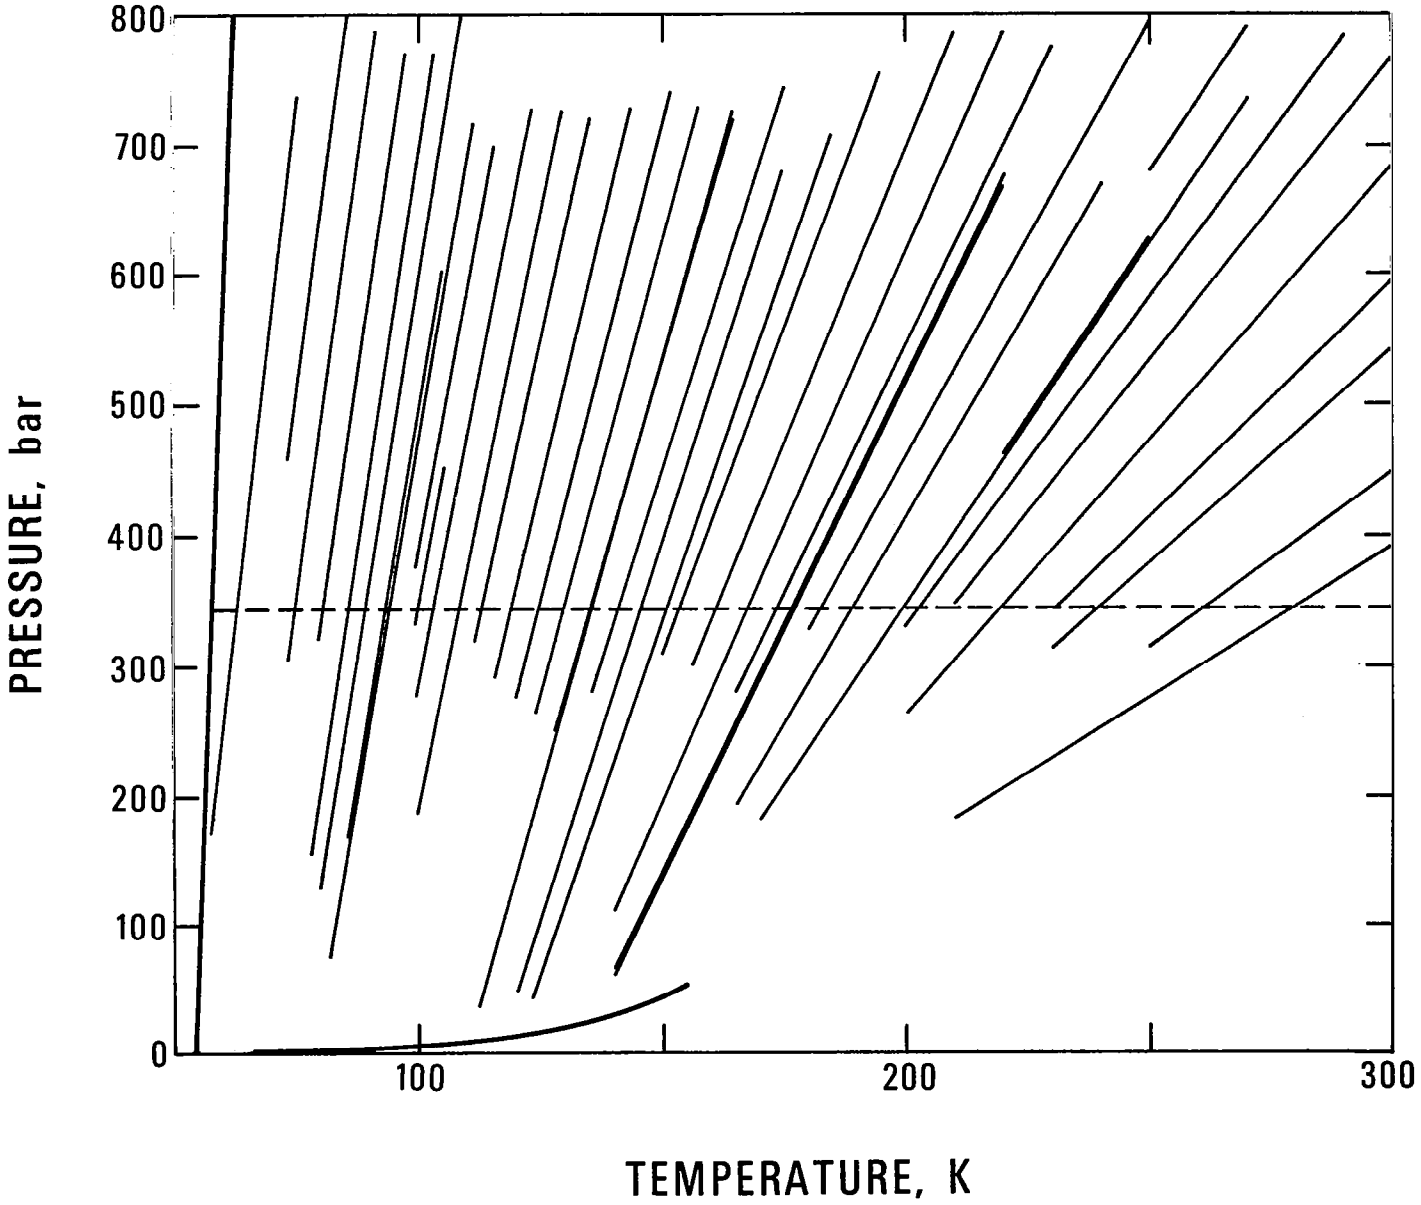

Figure 1. Experimental isochores. Dashed line indicates limit of earlier NBS data.

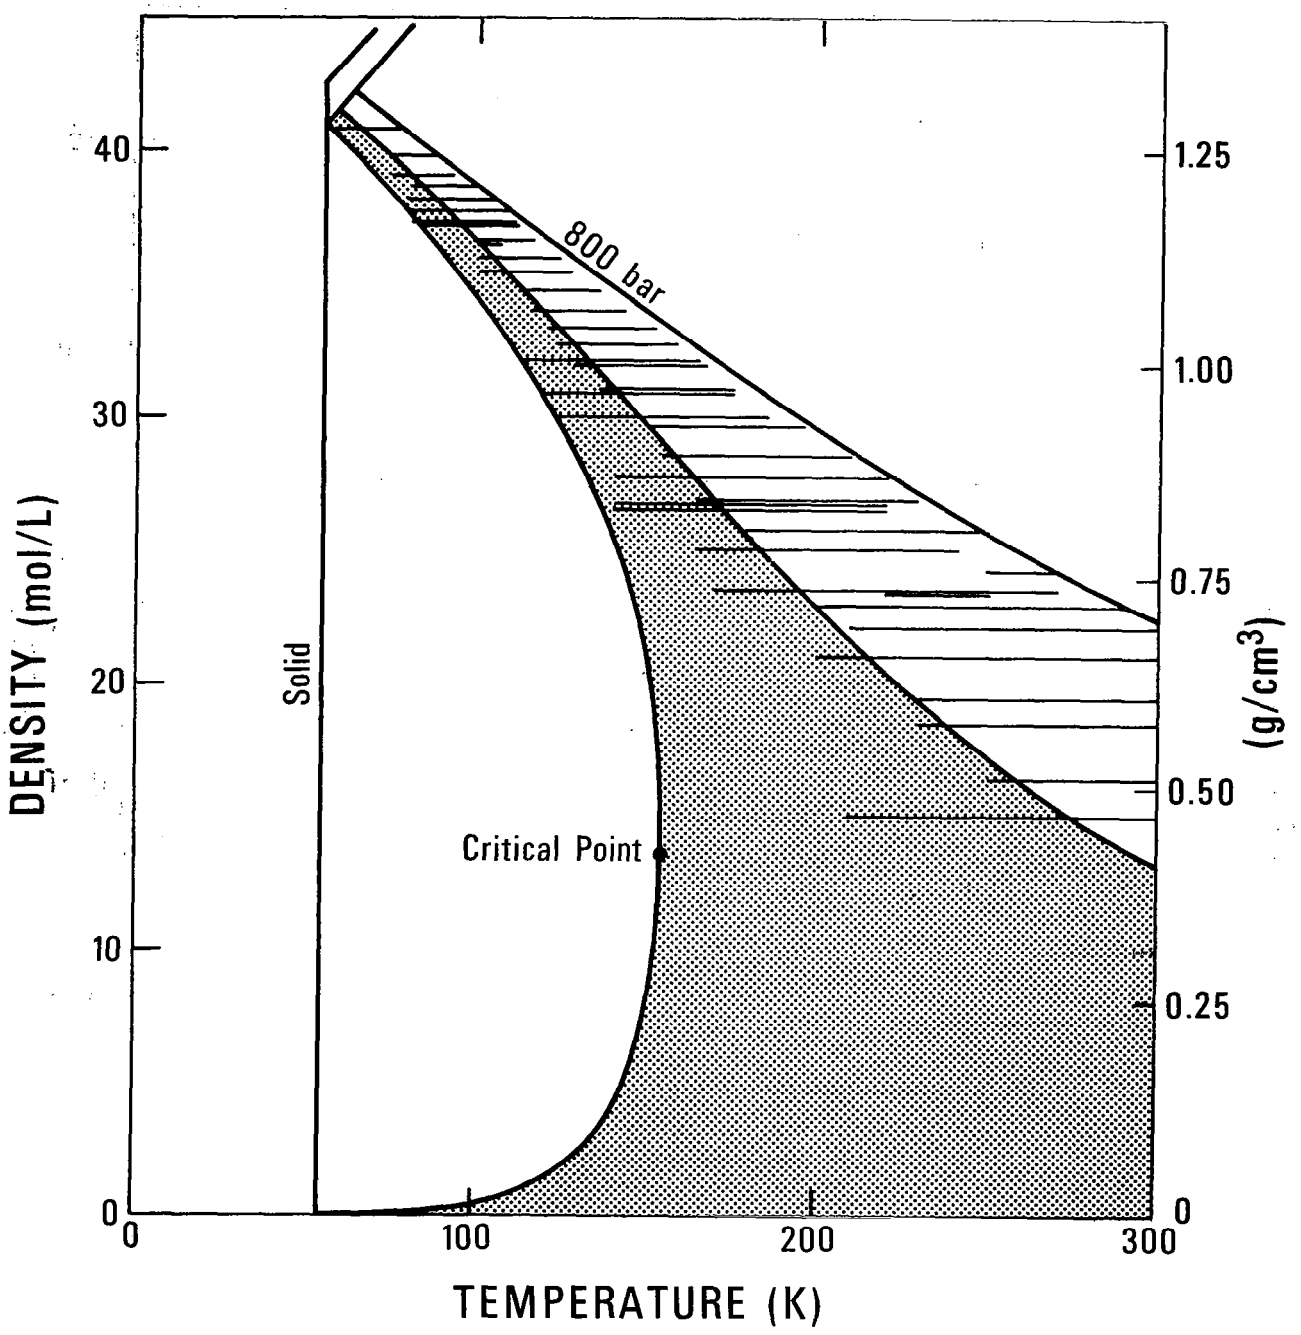

Figure 2. New experimental isochores (horizontal lines); shaded area shows the region of earlier NBS data.

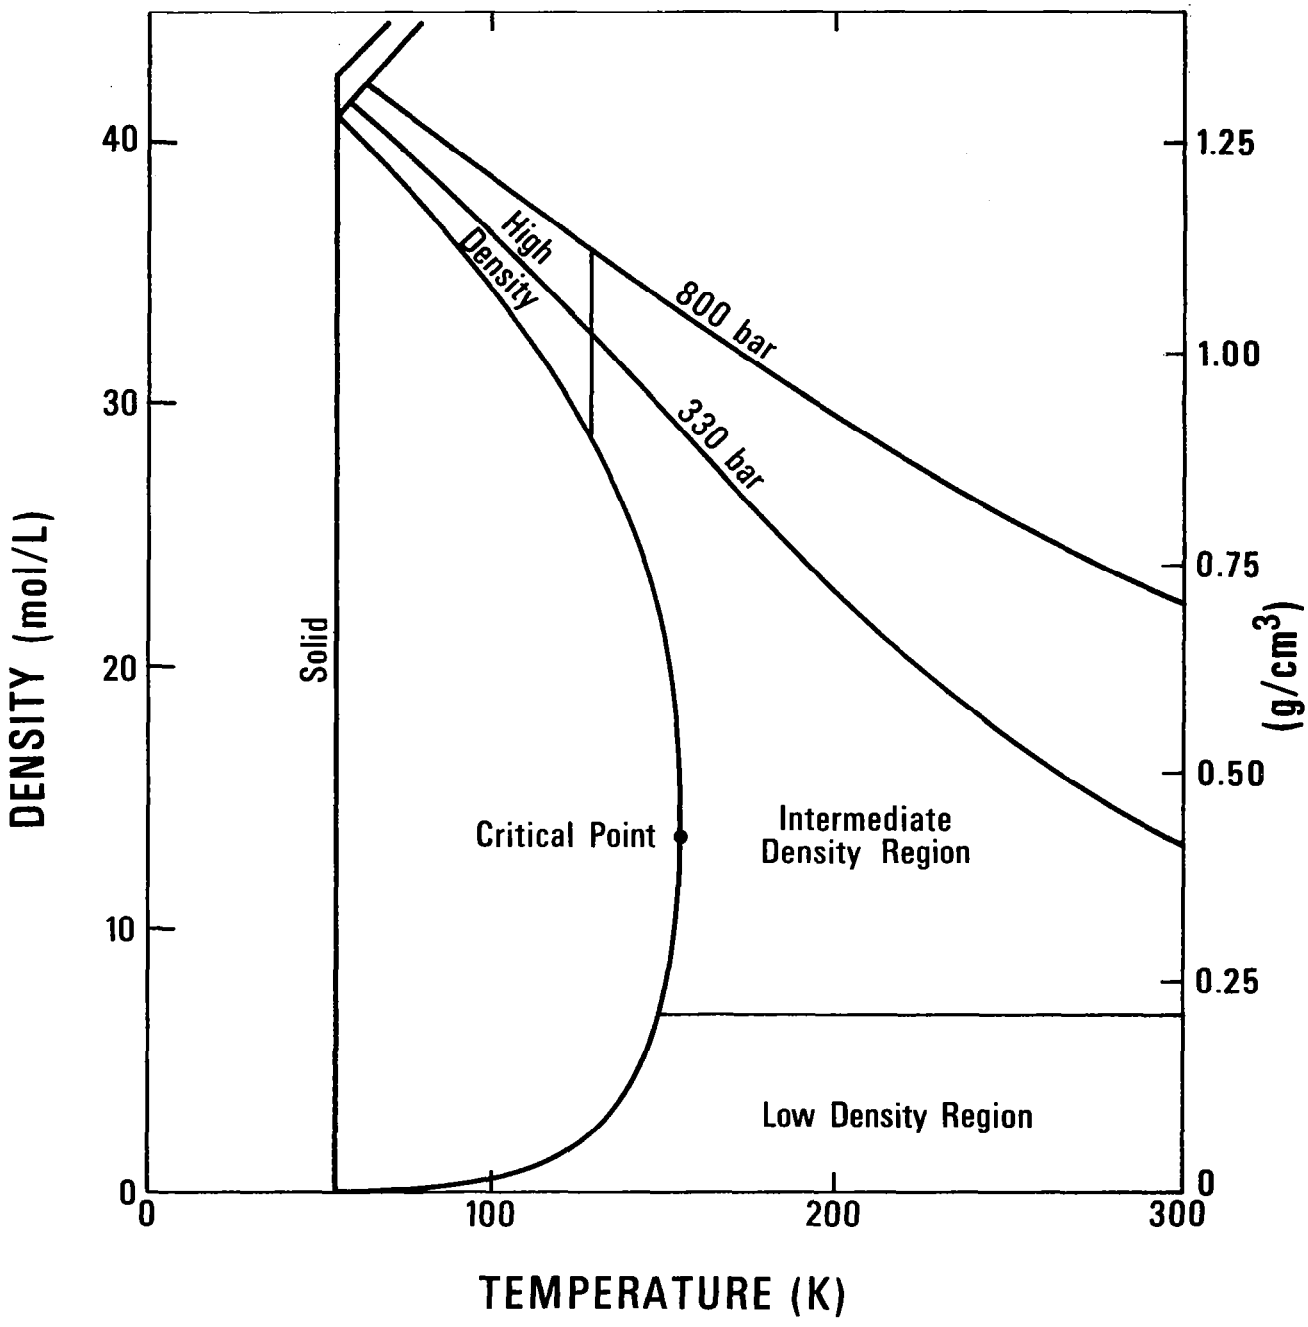

Figure 3. The three regions for representation of the data.

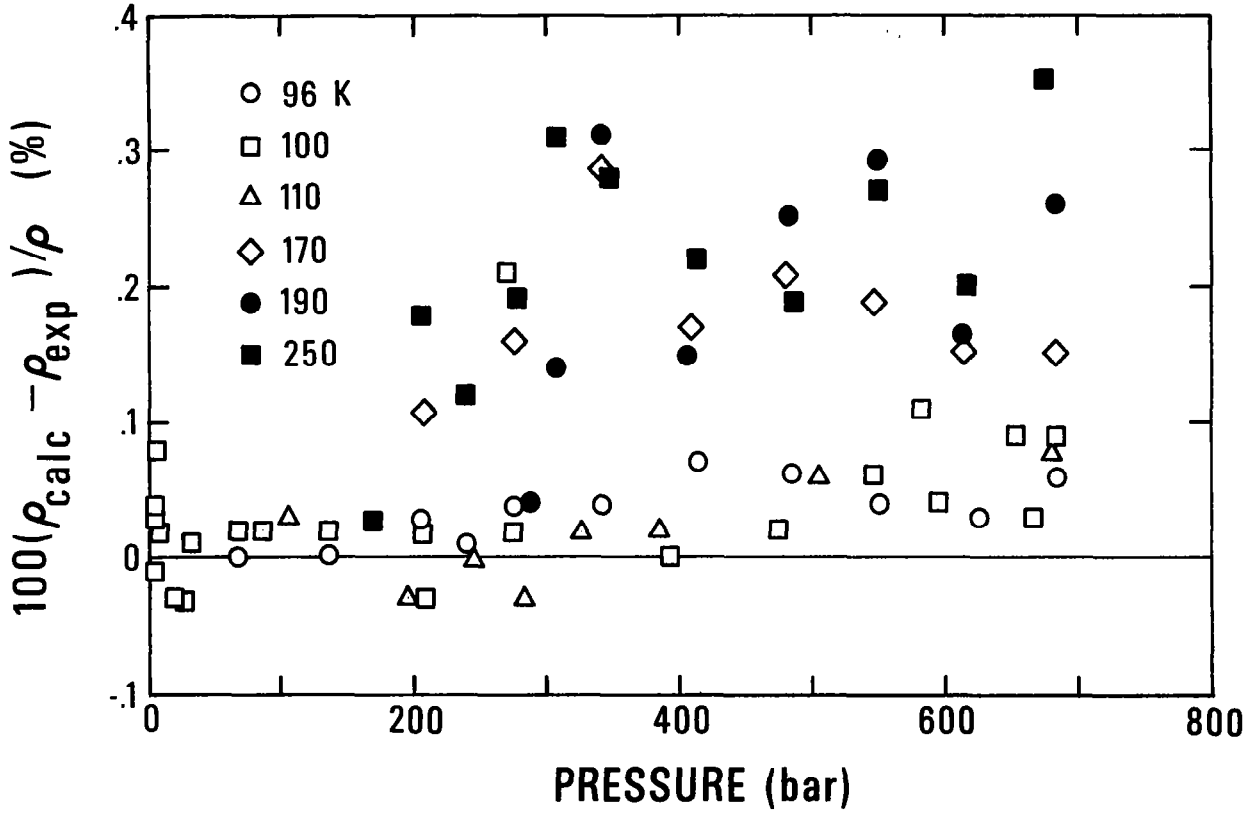

Figure 4. Comparison with the densities of Streett and Sagan [13].

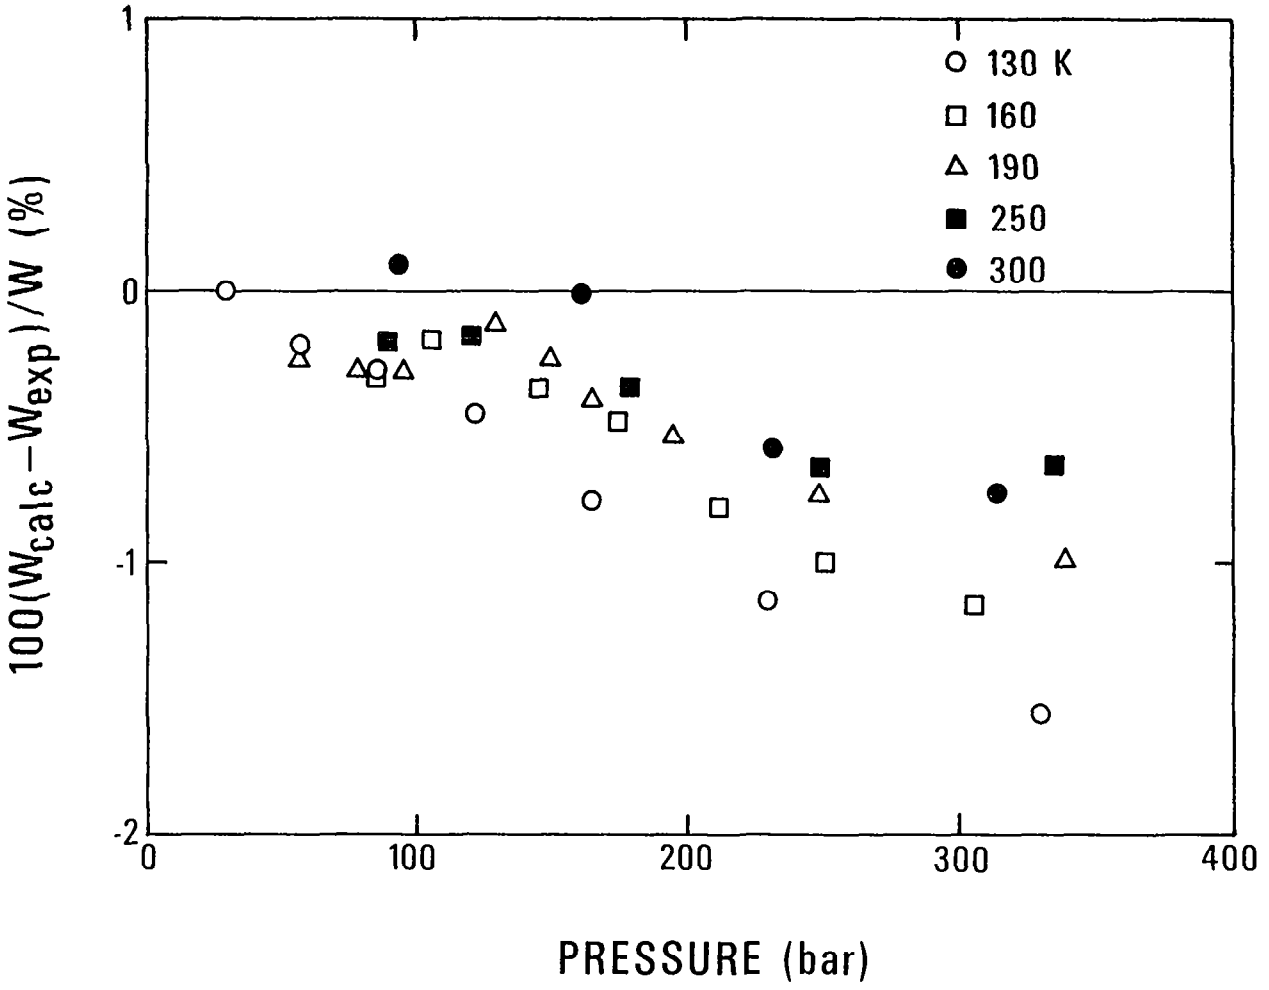

Figure 5. Comparison with the sound velocity data of Straty and Younglove [4].

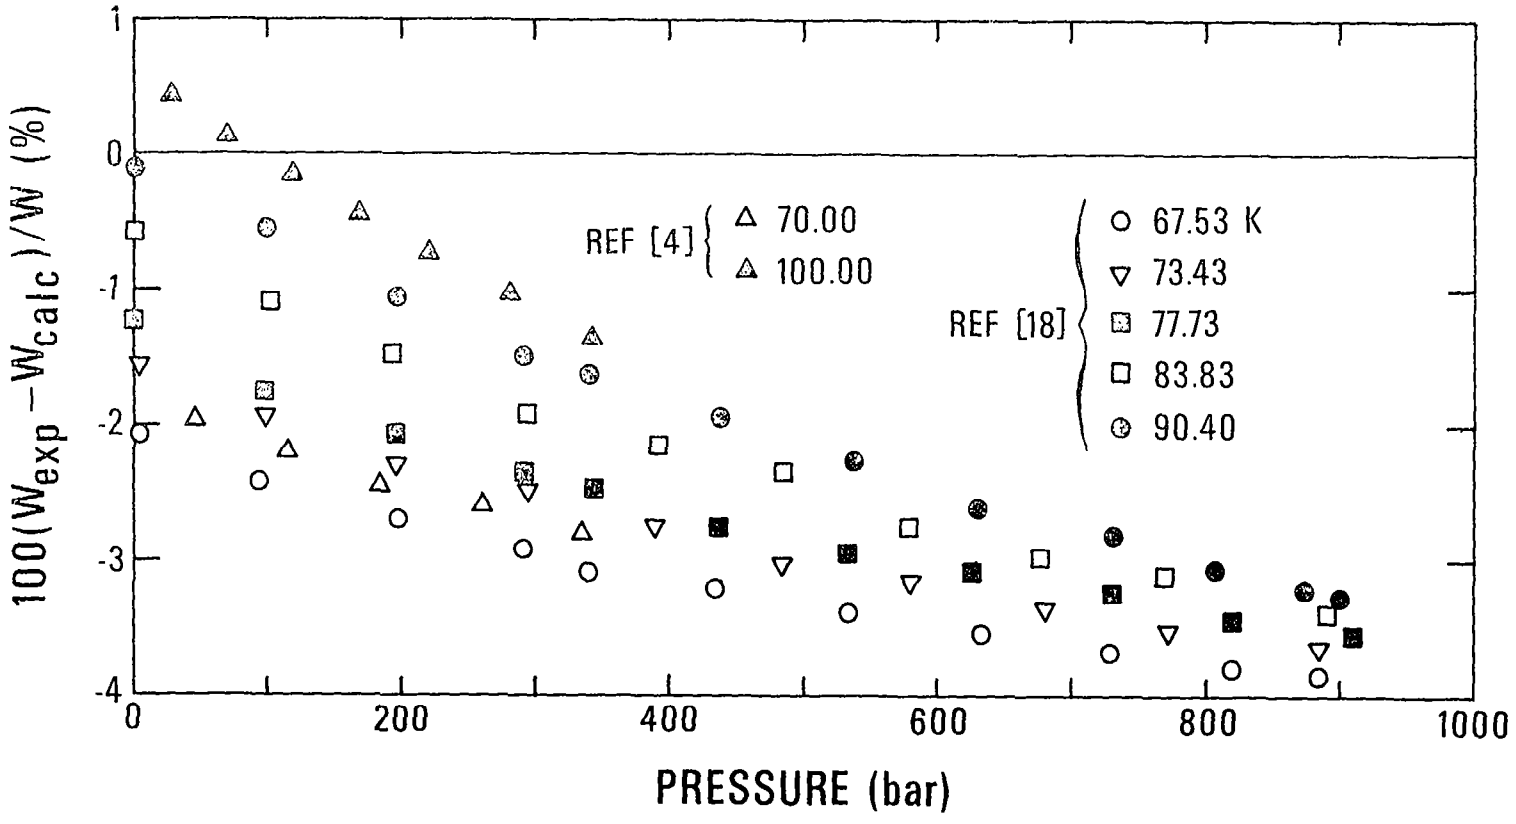

Figure 6. Comparison with experimental sound velocities in the compressed liquid.

	13. Type of Report and Period Covered
12. Sponsoring Agency Name and Address	Reference Publication
National Aeronautics and Space Administration Lewis Research Center, Mail Stop 301-1 Cleveland, OH 44135	14. Sponsoring Agency Code

15. Supplementary Notes

16. Abstract

NBS compressibility measurements and thermodynamic properties calculations for oxygen have been extended to higher pressures. The results of a new experimental program are presented in the form of PVT data in the temperature range 58 - 300 K at pressures up to 800 bar. Tables of the derived thermodynamic properties on isobars to 1000 bar are given, including density, internal energy, enthalpy, entropy, specific heats at constant volume and constant pressure, velocity of sound, and the surface derivatives $(\partial P/\partial T)_\rho$ and $(\partial P/\partial \rho)_T$. Auxiliary tables in engineering units are also given. The accuracy of the data is discussed and comparisons are made with previous data.

17. Key Words (Suggested by Author(s))	18. Distribution Statement
Density; Enthalpy; Entropy; Oxygen; Properties of fluids; Specific heat; Velocity of sound	Unclassified - unlimited STAR category 28

19. Security Classif. (of this report)	20. Security Classif. (of this page)	21. No. of Pages	22. Price*
